

Offboarding Workflow - Evaluation Summary

Purpose

This document accompanies a synthetic employee offboarding and access revocation workflow packet, used as a controlled test of an AI workflow readiness assessment. The assessment evaluates whether a documented workflow is a good candidate for AI-assisted automation: where AI may help, what should stay human-controlled, and which gaps to address first. It also reports how complete the submitted packet was. It had no access to this summary.

Evaluation result

Planted defects	Found	Partially caught	Missed	Correct lookalike items	False positives	Unplanted defects found
17	14	1	2	10	0	2

The packet passed spreadsheet validation cleanly. Nothing found was a formatting error or a broken reference. These are workflow, data, control, and AI-readiness issues a team would need to understand before pursuing automation.

The evaluation maps the report back to the planted-defect key. It is not the report's finding count, which merges some defects and adds unplanted ones.

The 17 planted defects

#	Defect	Result
1	Revocation is never verified against the target system; a closed ticket is treated as proof	Found
2	Manager attestation required by a control, captured by no step	Missed
3	Nothing establishes the litigation hold, so a gate exists with no step that closes it	Found
4	"A documented business need" is the entire standard for retaining access past departure	Found
5	"High-risk departures follow the expedited path" but high risk is never defined	Found
6	Four-hour revocation requirement with no defined start time and no completion field	Found
7	A status value for an unresponsive manager that no rule handles	Missed
8	Delete in 30 days versus retain for 3 years: two controls, no precedence rule	Found
9	The approval design guarantees the separation-of-duties violation	Partial
10	Five parallel revocation branches with nothing confirming all five completed	Found
11	Termination reason detail marked model-available, against three stated restrictions	Found
12	Personal email addresses marked model-available with no redaction	Found
13	The stated AI restrictions omit every irreversible action	Found
14	The expedited path is gated by an approval role that does not exist	Found
15	A declared system that no step uses	Found
16	A data field mapped to a step that does not use it	Found
17	A mailbox permanently deleted while under legal hold	Found

Findings beyond the evaluation key

The most interesting result was the two defects nobody planted. Real workflow documentation works the same way: the valuable findings are often the ones nobody knew to look for.

- **A stated AI goal with no data behind it.** The packet proposed flagging SaaS apps found in access logs but missing from the application directory. No log owner, matching key, coverage, or validation method is documented anywhere in the packet.
- **A reopened state with no process behind it.** The packet allows persistent-access cases to be reopened but never defines the trigger, owner, containment, verification, or reclosure rule.

What the assessment missed

This is a structured first pass, not a replacement for process owners, compliance, security, legal, or operational experts.

- Manager attestation is required by a control but was not raised as a standalone control-implementation defect.
- The unresponsive-manager status value appears inside broader closure findings, but not as a standalone missing-rule or disposition defect.
- Separation of duties was caught at the sample-record level, but the design-level conflict was not.

Reading the result. Planted defects show it finds known issues; unplanted ones show it finds issues nobody placed there; the misses show why the output needs review by people who know the process. Zero false positives matters as much: over-reporting trains people to ignore an assessment.
